Published Date: November 27, 2026 **Article DOI: 10.65150/EP-jefrr/V2E11/2026-21**

ABSTRACT: This study develops an analytical framework for the integrated orchestration and utilization of internal resources to sustain productivity in small and medium-sized enterprises (SMEs), focusing on human capital, financial resources, and quality management. Drawing on a review, analysis, and integration of the Resource-Based View (RBV), Resource Orchestration Theory (ROT), and Dynamic Capabilities Theory, the study clarifies the complementary relationships among these three resource domains and the mechanisms through which they are converted into operational capabilities. The analysis proposes an integrated resource orchestration capability comprising five components: resource identification and structuring, bundling, coordination, leveraging and transformation, and reconfiguration. The framework emphasizes that effective resource utilization depends not only on the availability of individual resources but also on an enterprise's ability to connect, coordinate, and adjust them in response to operational requirements. The study extends an integrated perspective on resource management in SMEs and offers managerial implications for improving resource-use efficiency over the long term.

KEYWORDS: Small and medium-sized enterprises, human capital, financial resources, quality management, resource orchestration.

1. INTRODUCTION

Small and medium-sized enterprises (SMEs) play an important role in generating employment and sustaining production and business activities. However, they often face disadvantages in access to capital, workforce quality, technology, and managerial capabilities. These constraints affect their ability to expand and maintain productivity amid competitive change. Syverson [1] shows that firm productivity is associated with management quality and production organization practices, while McKenzie and Woodruff [2] also identify a relationship between management practices and the performance of small firms. This suggests that productivity depends not only on firm size or the volume of resources owned, but also on how enterprises organize and deploy those resources.

The Resource-Based View (RBV) emphasizes the role of valuable, rare, inimitable, and non-substitutable resources in creating competitive advantage [3]. However, this approach primarily explains the strategic value of resources and does not fully clarify how they are organized and utilized in day-to-day operations. Resource Orchestration Theory (ROT) adds a managerial dimension through the processes of structuring, bundling, and leveraging resources [4], [5]. Dynamic Capabilities Theory, in turn, emphasizes an enterprise's ability to identify change, seize opportunities, and reconfigure resources to maintain adaptability [6], [7]. Combining these perspectives provides a basis for examining not only the value of individual resources but also how they are coordinated and transformed into operational capabilities.

Research on internal resources has developed along several relatively specialized streams. In the human capital literature, Wright, Dunford, and Snell [8] clarify the strategic role of human resources from an RBV perspective; Crook et al. [9] synthesize evidence on the relationship between human capital and firm performance; and Chowdhury et al. [10] examine the contribution of core employee-based human capital to revenue productivity in small firms. With regard to financial resources, Beck and Demirgüç-Kunt [11], and Beck, Demirgüç-Kunt, and Maksimovic [12], analyze financial constraints faced by SMEs, while Nguyen [13] examines the relationship between financial constraints and productivity in Vietnam's manufacturing industries. In the area of quality management, the studies by Kaynak [14], Samson and Terziovski [15], Hendricks and Singhal [16], and Sharma and Gadenne [17] provide evidence concerning the relationship between quality management practices and organizational performance. Overall, these research streams establish the importance of each resource domain, but do not fully explain the mechanisms through which all three domains complement and coordinate with one another in shaping SMEs' operational capabilities.

Although existing studies provide important insights into human capital, financial resources, and quality management, several issues concerning the relationships among these resource domains remain to be clarified. First, examining each resource separately does not fully explain differences in resource-utilization effectiveness among SMEs operating under relatively similar conditions. Second, the interaction and complementarity mechanisms among human capital, finance, and quality management have not been sufficiently specified within a unified analytical framework. In particular, the role of managerial capability in connecting decisions on staffing, investment, and quality, as well as in adjusting resource configurations when operating conditions change, requires further explanation. The research problem therefore lies not in determining which individual resource is more important, but in explaining how enterprises organize, coordinate, and transform complementary

resources into operational capabilities that can be sustained over time. This gap provides the rationale for developing an Integrated Resource Orchestration framework in the context of SMEs.

This study develops an integrated analytical framework for the orchestration and utilization of internal resources in SMEs, focusing on three resource domains: human capital, financial resources, and quality management. The article makes three contributions. First, it places the three resource domains within a complementary system rather than examining them independently. Second, it identifies resource orchestration capability as the central mechanism through which inputs are transformed into operational capabilities. Third, it specifies this mechanism through five components, adding reconfiguration to explain how productivity can be sustained as business conditions change. Accordingly, the study seeks to develop an analytical framework for the orchestration and utilization of internal resources in SMEs, clarify the characteristics and roles of the three resource domains, analyze their complementary relationships, and identify the managerial mechanisms through which resources are converted into operational capabilities and sustained productivity. The study adopts a theory-development approach based on literature synthesis and does not use enterprise survey data; therefore, the proposed framework remains conceptual and has not yet been empirically validated.

2. RESEARCH CONTENT

2.1. Research methodology

This study combines a literature review with theoretical analysis and synthesis to develop an analytical framework for internal resource orchestration in SMEs. The literature focuses on scholarly works concerning the Resource-Based View, Resource Orchestration Theory, Dynamic Capabilities Theory, human capital, access to finance, and quality management. Studies were selected according to their relevance to the research question, theoretical contribution, and capacity to provide a rationale for explaining the relationships among the three resource domains.

The analysis proceeded along three complementary lines. First, the theoretical foundations were compared to identify the distinct explanatory roles of RBV, ROT, and Dynamic Capabilities Theory. Second, studies on human capital, finance, and quality management were synthesized to identify the characteristics, impact mechanisms, and complementary relationships of the three resource domains. On this basis, the study connects the relevant theoretical arguments, develops the concept of integrated resource orchestration capability, identifies its components, and constructs a model explaining how resources are transformed into operational capabilities and sustainable productivity.

No primary data were collected; no enterprise survey was conducted; and no statistical tests were performed. Accordingly, the relationships in the model are presented as theoretical arguments and research propositions, rather than as causal relationships established through empirical testing.

2.2. Theoretical foundations and integration logic

The Resource-Based View (RBV) explains competitive advantage in terms of the resources owned and controlled by an enterprise. According to Barney [3], resources can generate sustained competitive advantage when they are valuable, rare, difficult to imitate, and non-substitutable. In this study, RBV provides a basis for identifying human capital, financial resources, and quality management systems as internal resources that can contribute to SME performance. However, the strategic value of a resource does not mean that it will automatically be converted into results. Its effective utilization also depends on how the enterprise organizes, combines, and deploys it in practice.

Resource Orchestration Theory (ROT) complements RBV by focusing on the role of managers in organizing and deploying resources. Sirmon, Hitt, and Ireland [4], together with Sirmon et al. [5], conceptualize this process through three interrelated groups of activities: resource structuring, resource bundling, and capability leveraging. Structuring concerns the acquisition, accumulation, and arrangement of resources; bundling combines resources to create or enhance capabilities; and leveraging focuses on mobilizing and deploying capabilities in business activities. ROT is particularly relevant to SMEs because it helps explain how enterprises set priorities, connect resources, and utilize them under resource constraints, rather than focusing solely on the scale of resources owned.

Dynamic Capabilities Theory adds a temporal and adaptive dimension by emphasizing the ability to identify change, seize opportunities, and reconfigure resources to maintain alignment with the business environment [6], [7]. Whereas ROT explains how managers structure, bundle, and leverage resources, Dynamic Capabilities Theory helps explain why enterprises need to adjust resource configurations as technology, market demand, and quality requirements change. Accordingly, this study uses RBV to identify the value of the resource domains, ROT to explain their orchestration and utilization, and Dynamic Capabilities Theory to incorporate learning, adaptation, and reconfiguration.

Table 1 summarizes the functions of the three theoretical foundations within the analytical framework.

Table 1. The roles of the theoretical foundations in the analytical framework

Theoretical foundation	Explanatory focus	Role in this study
RBV [3]	Strategic value of internal resources	Identifies human capital, financial resources, and organizational resources
ROT [4], [5]	Resource structuring, bundling, and leveraging	Explains the processes of organizing and coordinating resources
Dynamic capabilities [6], [7]	Identifying change and reconfiguring resources	Explains adaptability and the maintenance of productivity

Source: Compiled by the authors based on [3]–[7].

2.3. Internal resource domains and their complementarity

Human capital comprises employees' knowledge, skills, experience, and learning capacity. In SMEs, it is reflected directly in employees' ability to perform tasks, operate equipment, handle situations, detect errors, and participate in process improvement. Human capital contributes to productivity by improving labor efficiency, reducing processing time, and limiting production errors. Crook et al. [9] provide synthesized evidence

License: This is an open access article under the CC BY 4.0 license: https://creativecommons.org/licenses/by/4.0/

of the relationship between human capital and firm performance, while Chowdhury et al. [10] emphasize the role of core employee-based human capital in revenue productivity in small firms. However, the extent to which this resource can be utilized depends on training opportunities, practical experience, supporting equipment, and mechanisms for sharing and retaining organizational knowledge.

Financial resources include equity, borrowed funds, and cash flow generated from business operations. They provide the means to sustain operations, train employees, invest in equipment, adopt technology, and implement quality management activities. Beck and Demirgüç-Kunt [11], and Beck, Demirgüç-Kunt, and Maksimovic [12], identify financial barriers faced by small firms; Nguyen [13] examines the relationship between financial constraints and productivity in Vietnamese manufacturing industries. Nevertheless, access to capital does not necessarily imply effective use of capital. The value of financial resources depends on the quality of budget planning, investment prioritization, and alignment between financial decisions and requirements relating to personnel, equipment, and quality. For SMEs, allocating funds to bottlenecks that directly affect productivity is more meaningful than distributing resources thinly across activities.

In this study, quality management is conceptualized as an organizational resource comprising standards, control procedures, managerial knowledge, and improvement practices developed within the enterprise. It is reflected in work standardization, control of deviations, employee participation, and continuous improvement. The studies by Kaynak [14], Samson and Terziovski [15], Hendricks and Singhal [16], and Sharma and Gadenne [17] provide a basis for understanding the relationship between quality management practices and organizational performance. In SMEs, a quality system can create value only when supported by employees capable of implementing procedures and by sufficient financial resources to maintain equipment, provide training, and undertake improvement activities. Quality management should therefore not be treated merely as a compliance or certification requirement, but as an integral part of the enterprise's operational capability.

The three resource domains are complementary and interdependent in the organization of production and business activities. Financial resources enable recruitment and training, equipment investment, and the maintenance of quality systems; conversely, employee capabilities and management quality determine how effectively these investments are utilized. Quality management provides procedures and information on errors, costs, and performance, helping managers identify improvement needs and prioritize capital allocation. Employees implement, monitor, and improve processes, while the quality system helps convert individual experience into standardized organizational knowledge. These relationships indicate that overall performance depends not only on the quality of each resource but also on the degree of fit and complementarity among them. Resource management should therefore be addressed at the system level rather than through the isolated optimization of individual resources.

Table 2 summarizes the interactions among the three resource domains and the operational value expected from their coordination.

Table 2. Complementary relationships among the three internal resource domains

Resource relationship	Interaction mechanism	Expected operational value
Human capital–finance	Finance supports training and equipment; human capital determines the effectiveness of capital utilization	Improved investment effectiveness and labor productivity
Finance–quality management	Capital supports system establishment, maintenance, and improvement; quality data guide capital allocation	Fewer errors, less waste, and lower costs
Human capital–quality management	Employees implement, monitor, and improve processes; the quality system standardizes knowledge	More stable processes and improved output quality
Simultaneous interaction	Human capital, finance, and the quality system are appropriately aligned within the same operational configuration	Development of operational capability and support for sustained productivity

Source: Compiled and developed by the authors based on [8]–[17].

2.4. Integrated resource orchestration capability

By integrating RBV, ROT, and Dynamic Capabilities Theory, this study proposes the concept of integrated resource orchestration capability, defined as an enterprise's ability to identify, organize, combine, coordinate, leverage, and adjust internal resources in mutually complementary ways in order to develop operational capabilities and maintain resource-use efficiency over the long term. This concept emphasizes that the value of resources is determined not only by their availability but also by the enterprise's ability to connect them in a configuration suited to operational requirements. In SMEs, orchestration capability is reflected in the alignment of decisions concerning human resources, finance, and quality management, thereby limiting fragmented investment and strengthening the conversion of resources into operational outcomes.

Integrated resource orchestration capability is specified through five interrelated components. Resource identification and structuring refer to the ability to assess existing resources, identify gaps, and select options for supplementing or rearranging them. Resource bundling involves creating complementarities among resource domains, for example by linking employee training with equipment investment and the standardization of production processes. Resource coordination concerns connecting decisions on personnel, budgets, and production to ensure that resources are mobilized toward unified operational objectives. Resource leveraging and transformation refer to putting the resulting configuration into practice through task allocation, operation, control, and improvement, thereby creating specific operational capabilities. Finally, resource reconfiguration reflects the ability to adjust personnel, budgets, equipment, and procedures when technology, markets, or quality requirements change.

These five components are interrelated and do not necessarily follow a fixed linear sequence. In practice, enterprises may bundle and leverage resources simultaneously or return to reassess their configuration when operational bottlenecks emerge. Theoretically, this study adopts the three processes of structuring, bundling, and leveraging from ROT [4], [5], while clarifying coordination as the mechanism connecting managerial decisions across the three resource domains. Reconfiguration adds the adjustment dimension derived from Dynamic Capabilities Theory [6], [7]. The contribution therefore does not lie in replacing existing theoretical components, but in specifying and connecting them within

License: This is an open access article under the CC BY 4.0 license: https://creativecommons.org/licenses/by/4.0/

an analytical framework suited to the resource constraints and managerial characteristics of SMEs. These components are proposed at the conceptual level and do not yet constitute an established, empirically validated measurement scale.

Resource orchestration capability in SMEs is influenced by organizational size, resource constraints, and the concentration of decision-making authority in the business owner or a small core management team. A lean structure may facilitate communication and rapid decision-making, but it can also increase dependence on managers' individual capabilities and experience. Developing orchestration capability therefore requires leadership commitment, reliable management information, clear allocation of responsibilities, budget-allocation mechanisms based on operational bottlenecks, and a working environment that encourages employees to share experience and participate in improvement.

Table 3 presents the five components, their managerial content, and their expected manifestations in SMEs.

Table 3. Components of integrated resource orchestration capability in SMEs

Component	Managerial content	Manifestation in SMEs	Expected intermediate outcome
Identification and structuring	Assessing resources, identifying gaps, and arranging resources	Identifying requirements for personnel, capital, and the quality system	An appropriate resource configuration
Bundling	Creating complementarities among resources	Linking training with equipment investment and process standardization	A complementary resource bundle
Coordination	Connecting managerial decisions	Aligning workforce, budget, and production plans	Less fragmentation and inconsistency
Leveraging and transformation	Mobilizing resources in practical activities	Using skills, capital, and procedures to improve operations	Stronger operational capability
Reconfiguration	Adjusting resources as conditions change	Retraining, reallocating budgets, and changing procedures	Maintained adaptability

2.5. The mechanism through which internal resources are converted into sustainable productivity

In this study, sustainable productivity is understood as the ability to maintain and improve resource-use efficiency over the long term. It is reflected in labor productivity, the efficiency of capital and equipment use, output quality, and the ability to control waste. This approach emphasizes stability and productivity improvement over time; it should not be conflated with environmental productivity or sustainability understood broadly in terms of the economic, social, and environmental pillars.

Within the proposed framework, the three internal resource domains form a complementary input system; resource orchestration capability serves as the organizing and connecting mechanism; and operational capability represents an intermediate outcome before productivity is realized. The process begins with identifying existing resources and bottlenecks, followed by combining human capital, finance, and the quality system into an appropriate configuration. Decisions concerning personnel, budgets, and production are coordinated to ensure that resources are mobilized in an integrated manner and then put into practice through task allocation, operation, control, and improvement. Thus, orchestration capability does not create new resources in a material sense; rather, it enhances the ability to connect, use, and transform existing resources into the capacity to perform work.

Operational capability is reflected in the ability to organize work consistently, use labor, capital, and equipment efficiently, control errors, and address emerging problems. When skilled employees are assigned to appropriate processes and supported by necessary equipment, enterprises are better positioned to reduce processing time, limit errors, and improve efficiency. Similarly, when quality, cost, and performance data inform investment decisions, managers can identify loss-generating activities more accurately and prioritize resources for improvement. Productivity outcomes should therefore be assessed across several dimensions, including labor efficiency, the effective use of capital and equipment, output quality, and the extent of waste, rather than being measured solely by output volume.

The ability to sustain productivity depends on whether an enterprise can learn from operational outcomes and adjust its resource configuration. Information on efficiency, costs, and quality provides a basis for managers to reconsider training plans, investment decisions, and production organization. Knowledge sharing, root-cause analysis of errors, and process improvement reduce dependence on individual experience while strengthening organizational learning. When technology, products, or market requirements change, enterprises need to adjust personnel, budgets, and procedures to maintain an appropriate resource configuration. This process reflects the relationship between resource orchestration capability and adaptability as explained by Dynamic Capabilities Theory [7].

The proposed conversion mechanism does not imply that every combination of resources will produce positive outcomes. Effectiveness depends on the fit among resources, the quality of coordination, managerial capability, and environmental conditions. Investing in technology without employees capable of operating it, providing training without opportunities for practical application, or establishing a quality system without an adequate maintenance budget may all reduce the effectiveness of resource utilization. Orchestration capability should therefore be understood as an enabling mechanism for resource conversion, not as a factor that guarantees productivity growth under all circumstances. The relationships proposed in the framework require further empirical investigation.

2.6. The Integrated Resource Orchestration model and discussion of its contribution

Building on the theoretical arguments and the analysis of relationships among the three resource domains, this study proposes the Integrated Resource Orchestration model to explain how internal resources are transformed into operational capabilities and sustainable productivity in SMEs. The model comprises four interrelated elements: (i) an input resource system consisting of human capital, financial resources, and quality management; (ii) integrated resource orchestration capability, comprising five components; (iii) operational capability; and (iv) sustainable productivity outcomes. Within this structure, orchestration capability connects and organizes complementary resources, while operational capability represents the ability to deploy the resource configuration in actual business activities. Operational outcomes also generate feedback that enables enterprises to assess and adjust their resource configuration in subsequent cycles.

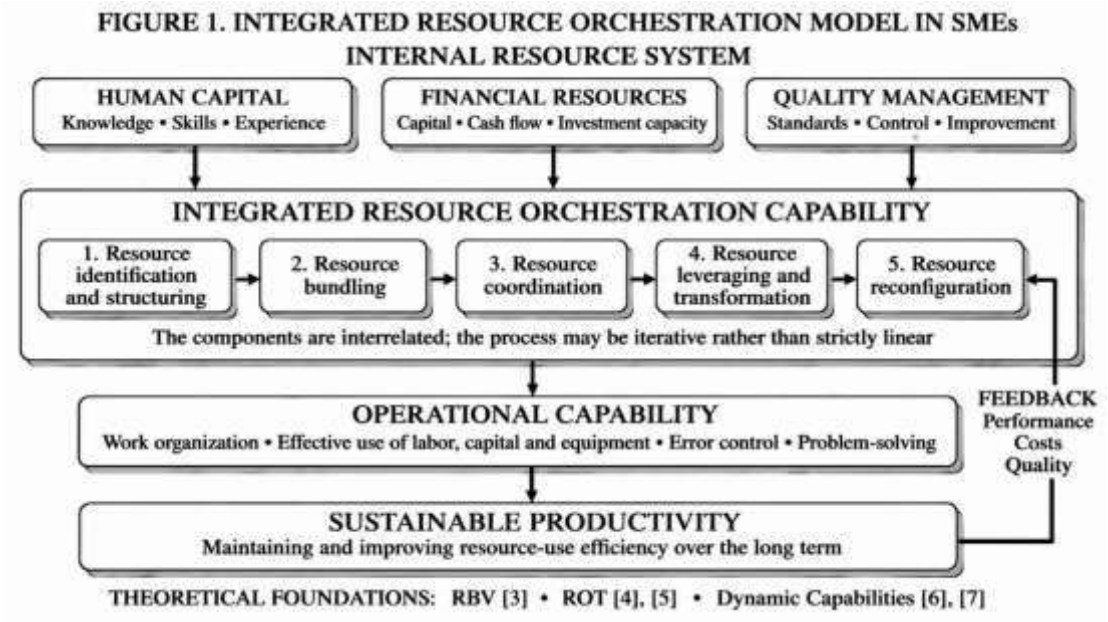

Figure 1. Integrated Resource Orchestration model in SMEs

Source: Proposed by the authors based on the synthesis of RBV [3], ROT [4], [5], and Dynamic Capabilities Theory [6], [7].

The model emphasizes the complementarity and interdependence of the three resource domains rather than treating their effects as independent. Human capital can realize its potential only when supported by appropriate financial resources and a suitable quality system. The effectiveness of financial investment depends on employees' ability to absorb, operate, and utilize the resources acquired, while quality management requires both personnel to implement it and financial resources to maintain and improve it. The quality system also generates information on errors, costs, and performance, helping managers adjust resource-allocation decisions. Resource orchestration is therefore positioned at the center of the model, representing the ability to connect complementary resources within a coherent operational configuration.

The theoretical contribution lies in developing an integrated approach to resource orchestration in the SME context. Rather than analyzing human capital, finance, and quality management separately, the study places these domains within a complementary configuration and highlights the interdependence among decisions on workforce development, capital allocation, and quality-system organization. Building on ROT, the study clarifies coordination as the mechanism connecting managerial decisions across resource domains and identifies leveraging and transformation as the bridge between resource configuration and operational capability. Integrating reconfiguration from Dynamic Capabilities Theory adds the dimension of resource adjustment in response to changes in the operating environment. The value of the framework therefore lies not in replacing its foundational theories, but in connecting and specifying their arguments in an explanatory structure suited to the resource constraints and lean management characteristics of SMEs. This is a conceptual contribution; the validity of the structure, the measurability of its components, and the relationships among them still require empirical testing.

From a managerial perspective, SMEs should move away from allocating resources within isolated functional areas and toward integrated planning across human resources, finance, and quality. Training plans should be linked to equipment-operation requirements and process control, while ensuring that employees have opportunities to apply their knowledge at work. Budgets should prioritize bottlenecks that directly affect efficiency, errors, and costs rather than being spread too thinly. Quality management systems should encourage employees to identify problems, analyze their causes, and propose improvements. Managers should use productivity, cost, and quality information to evaluate resource utilization and adjust personnel, budgets, and procedures as operating conditions change.

3. CONCLUSION AND RECOMMENDATIONS

This study develops an Integrated Resource Orchestration framework to explain how SMEs coordinate and utilize human capital, financial resources, and quality management to build operational capabilities and sustain productivity. The theoretical synthesis indicates that effective resource utilization depends not only on the availability of individual resources but also on the ability to organize, combine, and coordinate them within an appropriate configuration. Integrated resource orchestration capability is specified through five components: structuring, bundling, coordination, leveraging and transformation, and reconfiguration. Structuring, bundling, and leveraging build on ROT; coordination is clarified as the mechanism connecting managerial decisions; and reconfiguration incorporates the adaptive dimension of Dynamic Capabilities Theory. The

License: This is an open access article under the CC BY 4.0 license: https://creativecommons.org/licenses/by/4.0/

framework thus explains the process through which input resources are transformed into operational capabilities and productivity outcomes that can be sustained over time.

For SMEs, resource development should be pursued in an integrated manner. Enterprises should align training plans with investment plans and quality requirements; allocate budgets according to operational bottlenecks; strengthen employee participation in process control and improvement; and use productivity, cost, and quality information to adjust resource configurations. This approach can help reduce fragmented investment and improve resource-use efficiency under conditions of resource scarcity.

This study is limited to the development of an analytical framework based on theoretical synthesis and does not use empirical data to test the proposed relationships. Future research should develop and assess measures for the five components of orchestration capability, test the relationships among input resources, orchestration capability, operational capability, and productivity, and examine differences across industries, firm sizes, and levels of managerial maturity.
